paper: [arXiv.org/abs/2509.14732](https://arxiv.org/abs/2509.14732)

Motivation

(Effective) risk attitude: how a decision-maker chooses
among risky prospects (=lotteries).

A key determinant of many economic phenomena.

Examples:

prospects

projects

health-insurance plans

occupations

spouses

locations

Motivation

(Effective) risk attitude: how a decision-maker chooses
among risky prospects (=lotteries).

A key determinant of many economic phenomena.

In most economic contexts, chosen prospect is not all there is:

prospects	outside option
projects	job loss (for manager)
health-insurance plans	public option
occupations	retraining
spouses	divorce
locations	bailout (e.g. FEMA)

Questions

Framework:

$$\underbrace{\text{effective risk att.}}_{\text{observable}} = \underbrace{\text{'true' risk att.}}_{\text{unobservable}} + \underbrace{\text{effect of o.o.}}_{\text{unobservable}}$$

Identification: what do choices reveal about 'true' risk attitude?

- important for policy / welfare analysis
- Thm 1(i): 'true' is more risk-averse than effective.
- Thm 1(ii): nothing more can be learned.

Comparative statics: how does effective risk att. vary
with 'true' risk att. & o.o.? (Th'm 2)

Specialness: which transform'ns of a decision problem
necessarily reduce risk-aversion?

- adding an o.o.: yes by Th'm 1(i)
- any other transform'n: no! (Th'm 3)

Literature

Th'm 1(i) formalises idea that o.o. increases risk appetite.

An old idea. For example, Adam Smith (1776) argued that limited liability (o.o. = bankruptcy) increases risk-taking.

Details: slide 28. See also e.g. Jensen and Meckling (1976, section 4.1),
Golbe (1981, 1988),
Gollier, Koehl and Rochet (1997).

An important idea, e.g. for financial stability.

Th'ns 1(ii), 2, 3: no close parallels that we know of.

Broader literature

Various literatures recognise that

effective risk att. = ‘true’ risk att. + economic forces

Some economic forces that have been studied:

- background risk..... papers: slide 31
- contracts
 - employment..... papers: slide 32
 - financing papers: slide 33
- having an audience
 - career concerns..... papers: slide 34
 - disclosure Ben-Porath, Dekel and Lipman, 2018
- (in)flexibility papers: slide 35
- competition papers: slides 36–39

What is special about o.o.? (Theorem 3)

Plan

Setup and background

The outside-option model

How an o.o. shapes risk attitude (Proposition 1)

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

Setup

Alternatives: $x, y \in X \neq \emptyset$.

Risky prospects / simple lotteries: $p, q \in \Delta^0(X)$

$$:= \left\{ p : X \rightarrow [0, 1] : |\text{supp}(p)| < \infty \ \& \ \sum_{x \in \text{supp}(p)} p(x) = 1 \right\}$$

Preferences \succeq, \succeq' : complete transitive relations on $\Delta^0(X)$.

\succeq is EU iff $\exists u : X \rightarrow \mathbf{R}$ s.t. $p \succeq q \iff \int u dp \geq \int u dq$.

\hookrightarrow the function u is called risk attitude

$\hookrightarrow \alpha u + \beta$ is identified off \succeq ($\alpha > 0$ & $\beta \in \mathbf{R}$ unknown)

\succeq is less risk-averse than \succeq' iff $\forall x \in X$ & $\forall p \in \Delta^0(X)$,

$$x \succeq(\succ) p \implies x \succeq'(\succ') p.$$

Setup

Alternatives: $x, y \in X \neq \emptyset$.

Risky prospects / simple lotteries: $p, q \in \Delta^0(X)$

$$:= \left\{ p : X \rightarrow [0, 1] : |\text{supp}(p)| < \infty \ \& \ \sum_{x \in \text{supp}(p)} p(x) = 1 \right\}$$

Preferences \succeq, \succeq' : complete transitive relations on $\Delta^0(X)$.

\succeq is EU iff $\exists u : X \rightarrow \mathbf{R}$ s.t. $p \succeq q \iff \int u dp \geq \int u dq$.

\hookrightarrow the function u is called risk attitude

$\hookrightarrow \alpha u + \beta$ is identified off \succeq ($\alpha > 0$ & $\beta \in \mathbf{R}$ unknown)

u is less risk-averse than v iff $\forall x \in X$ & $\forall p \in \Delta^0(X)$,

$$u(x) \geq (>) \int u dp \implies v(x) \geq (>) \int v dp.$$

Pratt's theorem (part 1)

For $X \neq \emptyset$ and $u, v : X \rightarrow \mathbf{R}$, the following are equivalent:

(A) u is less risk-averse than v .

(B) \exists increasing convex $\phi : \text{co}(v(X)) \rightarrow \mathbf{R}$
that is strictly increasing on $v(X)$ & satisfies $u = \phi \circ v$.

(C) The following two properties hold:

(I) $\forall x, y \in X, u(x) \geq (>) u(y) \implies v(x) \geq (>) v(y)$.

(II) $\forall x, y, z \in X$, if $u(x) < u(y) < u(z)$, then

$$\frac{u(z) - u(y)}{u(y) - u(x)} \geq \frac{v(z) - v(y)}{v(y) - v(x)}.$$

Pratt's theorem (part 2)

If in addition X is an open convex subset of \mathbf{R}

& u, v are C^2 with $u' > 0 < v'$, then

u is less risk-averse than v iff $u''/u' \geq v''/v'$.

Plan

Setup and background

The outside-option model

How an o.o. shapes risk attitude (Proposition 1)

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

The outside-option model

Decision-maker has

- EU risk attitude $v : X \rightarrow \mathbf{R}$
- outside option worth $\sim F$.

o.o. may be unavailable, i.e. ‘worth $-\infty$ ’

$\implies F : \mathbf{R} \rightarrow [0, 1]$ is an extended CDF. (def’n: slide 29)

Decision-maker’s valuation of alternative $x \in X$:

$$\int \max\{v(x), k\} F(\mathrm{d}k) = F(v(x))v(x) + \int_{(v(x), +\infty)} k F(\mathrm{d}k).$$

(Compare realised o.o. with x ; if better, exercise.)

Where do outside options come from?

Physical o.o. $\sim \mu \in \Delta(Y \cup \{\emptyset\})$, ‘ \emptyset ’ means ‘unavailable’
payoff fn $w : Y \rightarrow \mathbf{R}$ convention: $w(\emptyset) := -\infty$
 $\implies F(k) := \mu(\{y \in Y \cup \{\emptyset\} : w(y) \leq k\}) \quad \forall k \in \mathbf{R}. \quad (\star)$

Special case: X -valued o.o., i.e. $Y = X$ & $w = v$.

- Implies F concentrated on $v(X) \cup \{-\infty\}$.
- Conversely, any ECDF F concentrated on $v(X) \cup \{-\infty\}$ arises via (\star) from some X -valued o.o. $\mu \in \Delta(X \cup \{-\infty\})$.
- (Detail: above makes sense provided $v(X)$ is Borel.)

(skip to slide 21)

Behavioural implications

Say that (v, F) is o.o. representation of \succeq iff

$$p \succeq q \iff \begin{cases} \int \left(\int \max\{v(x), k\} F(dk) \right) p(dx) \\ \geq \int \left(\int \max\{v(x), k\} F(dk) \right) q(dx). \end{cases}$$

Note: (v, F) o.o. rep'n of \succeq

$\implies \succeq$ is EU with risk att. u where $\exists \alpha > 0$ & $\beta \in \mathbf{R}$ s.t.

$$\alpha u(x) + \beta = \int \max\{v(x), k\} F(dk) \quad \forall x \in X.$$

$\hookrightarrow u$ is decision-maker's effective risk attitude.

Corollary: \succeq admits an o.o. representation iff \succeq is EU.

Plan

Setup and background

The outside-option model

How an o.o. shapes risk attitude (Proposition 1)

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

How an o.o. shapes risk attitude

Question: how do properties of o.o. dist'n F shape divergence of effective risk att. u from 'true' risk att. v ?

How an o.o. shapes risk attitude

Proposition 1. For $X \neq \emptyset$, $u, v : X \rightarrow \mathbf{R}$
& ECDF F
the following are equivalent:

(i) $\exists \alpha > 0$ & $\beta \in \mathbf{R}$ such that

$$\alpha u(x) + \beta = \int \max\{v(x), k\} F(\mathrm{d}k) \quad \forall x \in X.$$

(ii) $\int_{(0,+\infty)} k F(\mathrm{d}k) < +\infty$, and

$\exists \phi : \text{co}(v(X)) \rightarrow \mathbf{R}$ s.t. $u = \phi \circ v$,

ϕ is abs. cont's & $\phi' \propto F$.

How an o.o. shapes risk attitude

Proposition 1. For $X \neq \emptyset$, $u, v : X \rightarrow \mathbf{R}$
& ECDF F that is C^1 with $F > 0$ on $(\inf v(X), +\infty)$,
the following are equivalent:

(i) $\exists \alpha > 0$ & $\beta \in \mathbf{R}$ such that

$$\alpha u(x) + \beta = \int \max\{v(x), k\} F(\mathrm{d}k) \quad \forall x \in X.$$

(ii') $\int_{(0, +\infty)} k F(\mathrm{d}k) < +\infty$, and

$\exists \phi : \text{co}(v(X)) \rightarrow \mathbf{R}$ s.t. $u = \phi \circ v$,

ϕ is C^2 & $\phi''/\phi' = F'/F$.

Monetary alternatives

Suppose alternatives & o.o. are monetary:

- X is an open convex subset of \mathbf{R}
- u, v are C^2 with $u' > 0 < v'$
- $F = G \circ v^{-1}$ for ECDF G concentrated on $X \cup \{-\infty\}$.

Then (ii) on previous slide is equivalent to

$$\begin{aligned} \text{(ii'')} \quad & \int_{(0, +\infty)} v dG < +\infty \quad \text{and} \\ & u''/u' = v''/v' + G'/G. \end{aligned}$$

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

Revealed risk attitude

Question: what can be learned about v from observing choice among lotteries?

Revealed risk attitude

Question: what can be learned about v from $\alpha u + \beta$?

Revealed risk attitude

Theorem 1. For $X \neq \emptyset$ and bounded-above $u, v : X \rightarrow \mathbf{R}$ with u Lipschitz w.r.t. v ,^{*} the following are equivalent:

- (a) u is less risk-averse than v .
- (b) $\exists \alpha > 0, \beta \in \mathbf{R}$ & an ECDF F such that

$$\alpha u(x) + \beta = \int \max\{v(x), k\} F(\mathrm{d}k) \quad \text{for every } x \in X$$

& $F > 0$ on $(\underline{\inf} v(X), +\infty)$.[†]

^{*} $\exists L \geq 0$ s.t. $\forall x, y \in X, |u(x) - u(y)| \leq L|v(x) - v(y)|$.

[†]Ordinarily $\underline{\inf} A := \inf A$. The exception:

$\underline{\inf} A := \inf(A \setminus \{\inf A\})$ if $\inf A < \inf(A \setminus \{\inf A\}) \notin A$.

(Non-)identification of the o.o. dist'n

Question: what can be learned about F from observing choice among lotteries?

(Non-)identification of the o.o. dist'n

Question: what can be learned about F from $\alpha u + \beta$?

Answer: essentially nothing. (details: slide 30)

Plan

Setup and background

The outside-option model

How an o.o. shapes risk attitude (Proposition 1)

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

Comparative statics

Question: how does effective risk att. u vary with (v, F) ?

Comparative statics

Theorem 2. Fix $X \neq \emptyset$, $\hat{u}, \hat{v} : X \rightarrow \mathbf{R}$,
ECDF \hat{F} with $\hat{F} > 0$ on $(\inf \hat{v}(X), +\infty)$.
Suppose $\exists \hat{\alpha} > 0$ & $\hat{\beta} \in \mathbf{R}$ such that

$$\hat{\alpha}\hat{u}(x) + \hat{\beta} = \int \max\{\hat{v}(x), k\} \hat{F}(\mathrm{d}k) \quad \forall x \in X.$$

Assume $(\hat{v}(X) \text{ Borel and})$ \hat{F} concentrated on $\hat{v}(X) \cup \{-\infty\}$.

(a) Sps $\hat{v} = v$. Then \hat{u} is less risk-averse than u iff
 \hat{F} is better than F in the RHRO on $v(X) \setminus \{\sup v(X)\}$.

\hookrightarrow RHRO (reverse hazard rate order) on $K \subseteq \mathbf{R}$:
 $F(\ell)\hat{F}(k) \leq F(k)\hat{F}(\ell)$ for all $k < \ell$ in K .

(b) Sps $F \circ v = \hat{F} \circ \hat{v}$. Then \hat{u} is less risk-averse than u iff
 \hat{v} is less risk-averse than v .

$\hookrightarrow F \circ v = \hat{F} \circ \hat{v}$ means utility units change $(v \rightsquigarrow \hat{v})$
but physical o.o. dist'n $\mu \in \Delta(X \cup \{\emptyset\})$ held fixed.

(recall slide 12)

Plan

Setup and background

The outside-option model

How an o.o. shapes risk attitude (Proposition 1)

Identification (Theorem 1)

Comparative statics (Theorem 2)

What is special about o.o.? (Theorem 3)

Idea

Adding an o.o. to a decision problem transforms it by replacing each $x \in X$ with an x -contingent lottery. (Viz. lottery which returns x or the o.o., whichever is better.)

Another example of such transform'n: adding background risk.

Question: which transformations decrease risk-aversion?

- adding o.o.: yes, by Th'm 1.
- adding background risk: no, not in general.

Idea

Adding an o.o. to a decision problem transforms it by replacing each $x \in X$ with an x -contingent lottery. (Viz. lottery which returns x or the o.o., whichever is better.)

Another example of such transform'n: adding background risk.

Question: which transformations decrease risk-aversion?

Answer: only transform'ns that amount to adding an o.o.

The question, formally

Transform'n: replace each x with draw from measure μ_x on X .

'True' risk att. $v : X \rightarrow \mathbf{R}$ \rightsquigarrow effective risk att. $x \mapsto \int v d\mu_x$.

Question: given rich class \mathcal{V} of possible 'true' risk attitudes,
which families $(\mu_x)_{x \in X}$ have the property that
 $\forall v \in \mathcal{V}, \quad x \mapsto \int v d\mu_x$ is less risk-averse than v ?

The question, reformulated

Question: given rich class \mathcal{V} of possible ‘true’ risk attitudes, which families $(\mu_x)_{x \in X}$ have the property that $\forall v \in \mathcal{V}, \quad x \mapsto \int v d\mu_x$ is less risk-averse than v ?

Since u less risk-averse than $v \implies u, v$ ordinally equivalent, restrict to \mathcal{V} s whose members are mutually ordinally equivalent.

No other restrictions $\implies \mathcal{V}$ is an ordinal equivalence class.

Given such \mathcal{V} , fix $v_0 \in \mathcal{V}$ & embed X in \mathbf{R} via $x \mapsto v_0(x)$. Then $X \subseteq \mathbf{R}$ & \mathcal{V} is the set of all str. incr. f’ns $X \rightarrow \mathbf{R}$.

Question’: which families $(G_x)_{x \in X}$ of CDFs concentr’d on X have the property that \forall str. incr. $v : X \rightarrow \mathbf{R}$, $x \mapsto \int v dG_x$ is less risk-averse than v ?

The answer

Theorem 3. For non-empty Borel $X \subseteq \mathbf{R}$ with $\sup X \notin X$ & family $(G_x)_{x \in X}$ of CDFs concentrated on X , the following are equivalent:

- (a) \forall bounded str. incr. $v : X \rightarrow \mathbf{R}$,
 $x \mapsto \int v dG_x$ is less risk-averse than v .
- (b) \exists ECDF $G \left\{ \begin{array}{l} \text{concentrated on } X \cup \{-\infty\}, \\ \text{with } G > 0 \text{ on } (\inf X, +\infty) \end{array} \right\}$ such that

\forall bounded str. incr. $v : X \rightarrow \mathbf{R}$,

$\exists \alpha > 0$ & $\beta \in \mathbf{R}$ such that

$$\alpha \int v dG_x + \beta = \int \max\{v(x), v(y)\} G(dy) \quad \text{for every } x \in X,$$

where by convention $v(-\infty) := -\infty$.

Thanks!

Adam Smith on limited liability and risk-taking

From the *Wealth of Nations*.³

In a private copartnery, each partner is bound for the debts contracted by the company to the whole extent of his fortune. In a joint stock company, on the contrary, each partner is bound only to the extent of his share. This total exemption from trouble and from risk, beyond a limited sum, encourages many people to become adventurers in joint stock companies, who would, upon no account, hazard their fortunes in any private copartnery.

(back to slide 4)

³Pages. 740–1 in the Glasgow edition (Smith, 1776/1976).

Extended CDFs

Extended CDF: $k \mapsto \mathbf{P}(K \leq k)$ for a $[-\infty, +\infty)$ -valued random variable K .

Observation: $F : \mathbf{R} \rightarrow [0, 1]$ is an ECDF iff
increasing, right-continuous, $\lim_{k \nearrow +\infty} F(k) = 1$.

Expectation of meas'ble $g : [-\infty, +\infty) \rightarrow \mathbf{R}$ w.r.t. ECDF F :

$$\int g dF := \left(\lim_{k \searrow -\infty} F(k) \right) g(-\infty) + \int_{\mathbf{R}} g dF.$$

(back to slide 11)

(Non-)identification of the o.o. dist'n: details

Proposition 2. For $X \neq \emptyset$, $u : X \rightarrow \mathbf{R}$ & ECDF F , the following are equivalent:

(I) $\int_{(0,+\infty)} kF(dk) < +\infty$, and
if $\int_{(-\infty,0]} kF(dk) > -\infty$ then u is bounded below.

(II) $\exists \alpha > 0$, $\beta \in \mathbf{R}$, & $v : X \rightarrow \mathbf{R}$ such that

$$\alpha u(x) + \beta = \int \max\{v(x), k\} F(dk) \quad \forall x \in X.$$
